

Hadoop is also a framework. It is open source, Apache sponsored. It is free, just download & install. It is basically for storing & for processing huge data set not small data.

Hadoop is used for storing & processing huge data set with cluster of commodity hardware.

cluster is set of machine in a single LAN. commodity H/W cheap H/W like <sup>laptop</sup> laptop, PC etc. Because of using cheap H/W.

If I wanted to store 500TB, it needs 4-5 crore, but if it is cheap H/W then it will be 1-1.25 crore.

How you are storing data? HDFS } 2 Core Components.  
" you are processing of data? Mapreduce.

It is specially design a file system for storing huge data set with cluster of commodity H/W with streaming access pattern.

~~It is a sply designed~~

Write once & running anywhere (any platform) - Java.

Write once & read any no. of times but don't change content of the files, this is called streaming.

If I want to store 2KB of data into a 4KB space, so other 2KB space is wasted.

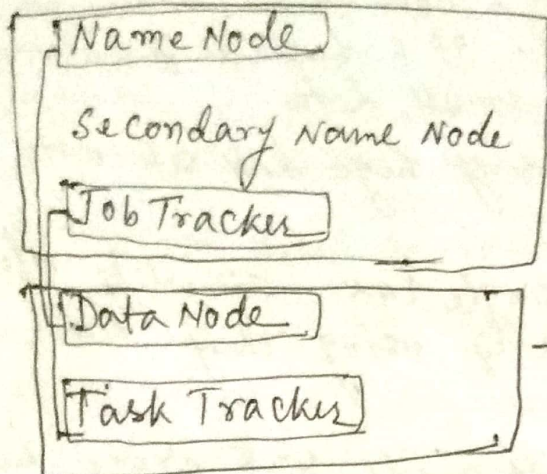

In HDFS by default the block size is 64MB. It is hardcoded by Hadoop install. After installing of HDFS if I want to store 35MB, so rest space is 29MB, & it is possible to use again. Changing of setting can extend 64MB to 128MB.

# HDFS has Five Services

→ It is run on background.

2

- Master service / Node.

- slave service / Node

Every Master service can talk each other  
" slave " " " " " " "

Name Node can talk to ~~Job Tracker~~ Data Node

Job Tracker " " " Task Tracker.

file name → file.txt.

client folder

200MB file  
500KB data.

wanted to store  
or processes some  
data

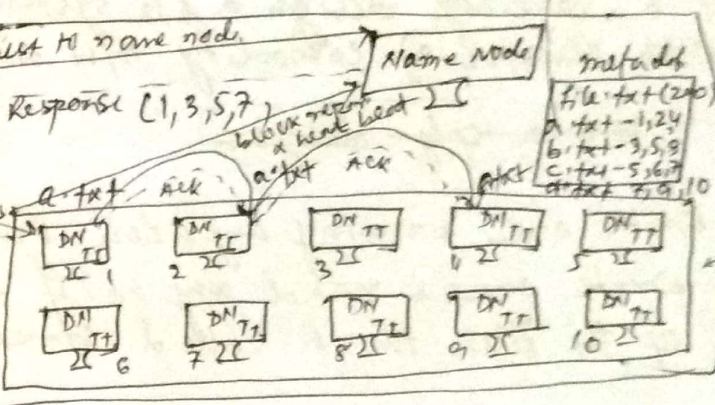

split into 10 of 64MB

Request to name node.

ACK

client approach to

ACK

input splits

clusters.

How many of block for  
200 MB file.  
64, 64, 64, 8

like a.txt 64  
b.txt 64  
c.txt 64  
d.txt 8 - 8 will be  
used for  
other.

To whom client should contact with,  
Ans - Name Node ; " " " "

for eg.

A Farmer  
having  
one field  
or small  
room.

1st year  
he generate  
10 rice packs.  
20 " " "  
50 " " "  
200 " " "

NOW it is not possible to store this room,  
so through <sup>them</sup> should keep in other ways

Like GDN.  
Room 90-50 - 1  
40-50 - 3  
50-100 - 7  
GDN  
white paper & filled all details  
the approaching a GDN with  
the help of laptop.  
Not possible to store directly,  
He has to approach GDN Manager.  
The Manager knows how many  
spaces are there, where are they.

My Manager, I have not enough space to  
store my rice packet, so you give me some space for storing rice.  
Manager ask how many packets are there and what quality of packet.  
My farmer go and store your packet in respective room.

3 Detail about data. Data about data is metadata.

Every data node is cheap H/W.

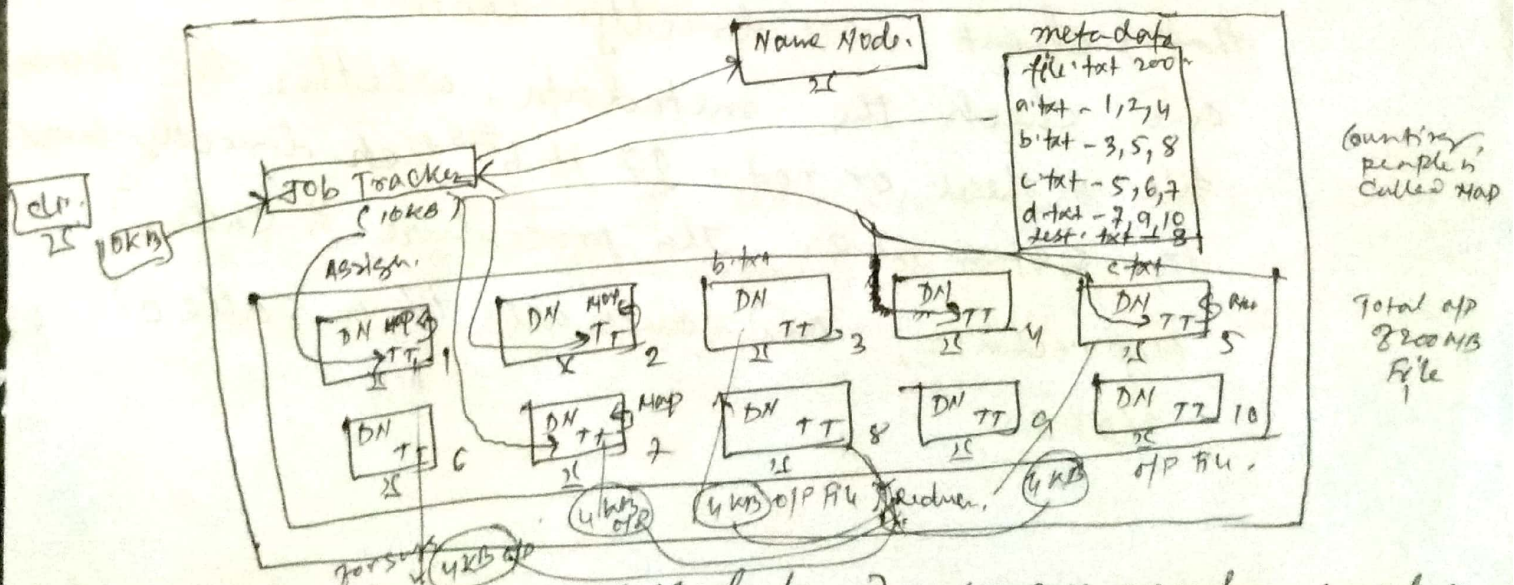

If the system is going to be down. To overcome this problem, this HDFS given 3 replication. Actually it had 600 MB file. The client has to know the replication. With the help of ack. How this NameNode <sup>can</sup> know ~~where~~ <sup>in which</sup> data is stored.

For every short period of time all the slave node give report to NameNode. block report a heart beat will give to Name node. 600 MB data has been occupied. (Still working & alive). Every data node have proper block report a heart beat

If any of the DN not giving proper block report a heart beat then, it says that it is dead. It has been removed. After removing, 2 replica will be available, and they will provide report properly. Fraction of second 3rd replica will be create.

If the metadata is lost, simply say that, there is no use of Hadoop. DN are cheap H/W but NN should be high end system or high reliable H/W. If NN is not working then no metadata will work. Keeping of metadata req. good NN, but actual storage is DN. If we use 4KB of block, have to maintain 4KB of metadata, so more space will req. NN is calling as single point of failure.

So, If Client want to store data, he has to contact with NN.

Store data & process data. For process need map reduce. 10KB of prog. to process of 200 MB data. Data should be brought to your local machine. But in this case 10KB will send to Data Name. This will help by Job tracker: Job tracker send msg to Name Node.

Jobtracker is used to assigning <sup>task</sup> job to tasktracker. In system no 1, 2, 4 the data is available, but nearest should be chosen by jobtracking. So time will take less if choose nearest one. After taking task by tasktracker, computation will start, so it is called Map. Four sub files is called input splits. Those many of no. Mappers will be there, that many no. of input splits there.

If the 1st is going down, then data will be lost, tasktracker will disturb. So this task will be reassign to another replica.

How the jobtracker know whether is dead or alive? or tasktracker is working or not. All the tasktracker send heartbeat to jobtracker. Every 3 sec tasktracker give heartbeat, and after 10 time waiting if NameNode is not getting any report, that means its dead or slow. Some time max task may use for different blocks so, tasktracker will work slowly. So, for that situation jobtracker assign task to fast way system, because of less tasktracking will working on, so it will take less time.

Reducer will combine all mapper o/p. And it the actual o/p for 200 MB of data. Reducer will take care of that. Client is directly approach to system no. 8 and he is going put back to o/p. before that, client will directly contact to NameNode and check the metadata, whether the task file is there or not. If it is <sup>there</sup> then directly connect to system no. 8. This procedure is called Mapreduce, and overall it is called HDFS.
